20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

A computer code for a turbulent boundary-layer, inviscid interaction method for axi-symmetric configurations of the type used for isolated nozzle afterbody models is presented. The method is applicable to flows with subsonic free streams, including slightly supercritical flows. The method consists of an integral boundary-layer method and a finite-difference inviscid-flow method which are coupled iteratively through the boundary-layer displacement thickness. Both attached and separated boundary layers can be

inviscid flow

20. ABSTRACT (Continued)

calculated. An option is provided for calculating two-dimensional boundary layers. The procedure for separated flows is to specify the displacement thickness of the boundary layer and calculate the free-stream velocity distribution from both the boundary-layer equations and the inviscid-flow equations. The separation point location and the angle of the displacement surface are found by an iterative procedure. The equations programmed are presented along with detailed instructions for the preparation of input data, description of the program output and instructions for operation of the program on an IBM 370 computer. Sample cases are provided for a complete axisymmetric interaction calculation and for a two-dimensional boundary-layer calculation.

PREFACE

The results reported herein were developed for the Arnold Engineering Development Center by Nielson Engineering and Research, Inc. under Contract F40600-76-C-0009. The author of this report was Gary D. Kuhn. The Air Force Project Engineer for this contract was E. R. Thompson, AEDC/DYR. The Program Element Number was 65807F. This report covers the work done during the period 15 March 1976 to 15 April 1977. The reproducibles used in the reproduction of this report were provided by the author.

1.0 INTRODUCTION

One of the critical areas in the design of both aircraft and missiles is the interaction between propulsive jets and the external flow over the aerodynamic shapes from which they issue. The drag of the afterbody and exhaust nozzle can be a significant fraction of the total vehicle drag. In order to obtain knowledge of the afterbody and nozzle flow fields and their interaction as early as possible in the design procedure, it is desirable to have a computational method for accounting for the viscous flow over the afterbody including separation and reattachment of the flow. Such a method should also account for the interaction between external inviscid flow over the afterbody and the viscous afterbody flow (including separated boundary layers).

This report describes a method for predicting the viscous flow field about an axisymmetric body at zero angle of attack. The method combines a finite-difference, inviscid-flow method with an integral boundary-layer method. The major difficulties in extending existing boundary-layer technology to flow on axisymmetric afterbodies are the same as those encountered in two-dimensional flows. First, a model for the turbulent Reynolds stresses must be employed. For the kind of bodies of interest herein, an eddy-viscosity model has been found which adequately accounts for the Reynolds stresses. For afterbody-nozzle configurations, the effect of the jet plume, boundary-layer, inviscid-flow interaction is also of major importance. Accounting for this interaction is a difficult problem. In the work described herein, the jet plume is simulated by a

solid body. Thus, the boundary-layer calculation involves separation on the boattail section of the afterbody with subsequent reattachment on the simulated plume.

The remainder of this report describes briefly the equations which are the basis of the calculative method and the particular technique used to calculate the viscous-inviscid interaction. Then the computer programs are described, followed by detailed instructions for the use of the programs. The composite computer program described herein contains the boundary-layer program developed for this work and an inviscid-flow program which is essentially the same as that described in reference 1. programs are incorporated as subprograms into a mainline program which performs an iteration to calculate the interaction between the boundary layer and inviscid flow for axisymmetric bodies of the type used for nozzle boattails followed by a solid plume simulator. The programs are written in the FORTRAN programming language for use on an IBM 370 computer. The boundary-layer program retains the capability to calculate two-dimensional flows as an option. Both the boundary-layer program and the inviscid-flow program can be used individually, without iterating if so desired.

2.0 DEVELOPMENT OF BOUNDARY-LAYER METHOD

The complete derivation of the governing equations for the boundary layer has been presented in reference 2. In this report the derivation is summarized and modified for the application of interest herein.

2.1 ASSUMPTIONS

The analysis is based on the following assumptions:

 The governing equations are those for a compressible turbulent boundary layer.

- 2. The air behaves as an ideal gas.
- 3. The molecular viscosity, μ_{t} , is proportional to the temperature.
- 4. The specific heat of the gas is constant.
- 5. The wall is either two dimensional or axisymmetric, but can have arbitrary profile in the direction of flow as long as the longitudinal radius of curvature of the wall is large compared to the boundary layer.
- 6. The pressure is constant normal to the wall.
- 7. The wall temperature is constant.

2.2 BOUNDARY-LAYER EQUATIONS FOR COMPRESSIBLE TURBULENT FLOW

The basic notation and coordinate scheme are shown in figure 1.3 Note that the same symbols are used for the physical coordinates of both two-dimensional and axisymmetric configurations. Thus, r denotes the distance of a point from the axis of an axisymmetric configuration, or from the reference plane of a two-dimensional configuration, x is the distance along the axis, or reference plane measured from the leading edge, and the dimension y is measured from the body surface normal to the axis.

The governing equations describing the steady flow of a compressible turbulent boundary layer for both two-dimensional and axisymmetric configurations are:

Continuity

$$\frac{\partial}{\partial x} (r^{k} \rho u) + \frac{\partial}{\partial y} [r^{k} \rho (v - r'_{w} u)] = 0$$
 (1)

Momentum

$$\rho \mathbf{u} \cdot \frac{\partial \mathbf{u}}{\partial \mathbf{x}} + \rho \left(\mathbf{v} - \mathbf{r}_{\mathbf{w}} \mathbf{u} \right) \cdot \frac{\partial \mathbf{u}}{\partial \mathbf{y}} = -\frac{\mathrm{d}\mathbf{p}}{\mathrm{d}\mathbf{x}} + \frac{1}{r^{k}} \cdot \frac{\partial}{\partial \mathbf{y}} \left(\mathbf{r}^{k} \mu \beta \cdot \frac{\partial \mathbf{u}}{\partial \mathbf{y}} \right) \tag{2}$$

Energy

$$\rho \mathbf{u} \frac{\partial \mathbf{S}}{\partial \mathbf{x}} + \rho \left(\mathbf{v} - \mathbf{r}_{\mathbf{w}}^{\dagger} \mathbf{u} \right) \frac{\partial \mathbf{S}}{\partial \mathbf{y}} = \frac{1}{\mathbf{r}^{\mathbf{k}}} \frac{\partial}{\partial \mathbf{y}} \left[\mathbf{r}^{\mathbf{k}} \left(\mu \left[\frac{1}{P} + \frac{1}{P_{\mathbf{T}}} \left(\beta - 1 \right) \right] \frac{\partial \mathbf{S}}{\partial \mathbf{y}} \right] \right] + \mu \left[\beta \left(1 - \frac{1}{P_{\mathbf{T}}} \right) + \frac{1}{P_{\mathbf{T}}} - \frac{1}{P} \right] \frac{\mathbf{u}}{H_{\mathbf{e}}} \frac{\partial \mathbf{u}}{\partial \mathbf{y}} \right]$$
(3)

where k=0 for two-dimensional flow and k=1 for axisymmetric flow, $r_{W}^{'}$ is the derivative of the body radius with respect to x, and

$$S = \frac{T_t}{T_{t_e}} - 1 \tag{4}$$

Equations (1), (2), and (3) are easily applicable to laminar and transitional flow. In laminar flow, substitution of $\beta = P_T = 1$ reduces the equations to those for a laminar boundary layer. Further, suitable variation of the eddy viscosity and turbulent Prandtl number makes the equations applicable to the transition region.

The boundary conditions for this system of equations are:

$$y = 0:$$

$$u = v = 0$$

$$r = r_{w}$$

$$S = S_{w}$$

$$u = u_{e}(x)$$

$$\frac{\partial u}{\partial y} = 0$$

$$v = v_{e}(x)$$

$$S = 0$$

$$x = x_{o}:$$

$$u = u_{o}(y)$$

$$S = S_{o}(y)$$

2.3 TRANSFORMATION OF AXISYMMETRIC BOUNDARY-LAYER EQUATIONS TO ALMOST TWO-DIMENSIONAL FORM

In order to put the axisymmetric equations (k = 1) into a more convenient form, the Probstein-Elliott transformation (ref. 3) is applied. The coordinates of the axisymmetric body are shown in figure 1. The Probstein-Elliott transformation is

$$d\tilde{\mathbf{x}} = \left[\frac{\dot{\mathbf{r}}_{\mathbf{w}}(\mathbf{x})}{\mathbf{L}}\right]^{2} d\mathbf{x} \tag{5}$$

$$d\tilde{y} = \frac{r(x,y)}{L} dy$$
 (6)

where $r_w(x)$ is specified by the body shape and r(x,y) is given by

$$r(x,y) = r_w(x) + y$$
 (7)

The transformed continuity equation has the form

$$\frac{\partial (\rho \tilde{\mathbf{u}})}{\partial \tilde{\mathbf{x}}} + \frac{\partial (\rho \tilde{\mathbf{v}})}{\partial \tilde{\mathbf{y}}} = 0 \tag{8}$$

where

n anois

$$\rho \widetilde{\mathbf{u}} = \rho \mathbf{u}$$
 (9)

and

$$\rho \tilde{\mathbf{v}} = -\frac{\partial \tilde{\psi}}{\partial \tilde{\mathbf{x}}} = \frac{\mathbf{r} \mathbf{L}}{\mathbf{r}_{\mathbf{w}}^{2}} \rho \left(\mathbf{v} - \mathbf{r}_{\mathbf{w}}^{\dagger} \mathbf{u} \right) + \frac{\mathbf{L}^{2}}{\mathbf{r}_{\mathbf{w}}^{2}} \frac{\partial \tilde{\mathbf{y}}}{\partial \mathbf{x}} \rho \mathbf{u}$$
 (10)

Applying the transformation to the momentum and energy equations (2) and (3) yields the transformed equations

$$\rho \tilde{\mathbf{u}} \frac{\partial \tilde{\mathbf{u}}}{\partial \tilde{\mathbf{x}}} + \rho \tilde{\mathbf{v}} \frac{\partial \tilde{\mathbf{u}}}{\partial \tilde{\mathbf{y}}} = -\frac{\mathrm{d}\mathbf{p}}{\mathrm{d}\tilde{\mathbf{x}}} + \frac{\partial}{\partial \tilde{\mathbf{y}}} \left[(1 + k \mathsf{t} \tilde{\mathbf{y}}) \mu \beta \frac{\partial \tilde{\mathbf{u}}}{\partial \tilde{\mathbf{y}}} \right] \tag{11}$$

$$\rho \tilde{\mathbf{u}} \frac{\partial \mathbf{S}}{\partial \tilde{\mathbf{x}}} + \rho \tilde{\mathbf{v}} \frac{\partial \mathbf{S}}{\partial \tilde{\mathbf{y}}} = \frac{\partial}{\partial \tilde{\mathbf{y}}} \left[(1 + kt\tilde{\mathbf{y}}) \left(\mu \mathbf{A} \frac{\partial \mathbf{S}}{\partial \tilde{\mathbf{y}}} + \mu \frac{\mathbf{B}}{\mathbf{H_e}} \tilde{\mathbf{u}} \frac{\partial \tilde{\mathbf{u}}}{\partial \tilde{\mathbf{y}}} \right) \right]$$
(12)

where

$$A = \frac{1}{P} - \frac{1}{P_{T}} + \frac{\beta}{P_{T}}$$
 (13)

$$B = \beta - \frac{\beta}{P_{T}} + \frac{1}{P_{T}} - \frac{1}{P}$$
 (14)

and t is the transverse curvature factor

$$t = \frac{2L}{r_w^2} \tag{15}$$

and, from equations (6) and (7),

$$\widetilde{\mathbf{y}} = \frac{\mathbf{r}_{\mathbf{W}}}{\mathbf{L}} \mathbf{y} + \frac{1}{2\mathbf{L}} \mathbf{y}^2 \tag{16}$$

For flows in which the transverse curvature terms are negligible, letting k=0 in equations (11) and (12) produces the equations of a two-dimensional boundary layer. The transverse curvature terms may be negligible for an axisymmetric flow if the body radius is large compared to the boundary-layer thickness. The Probstein-Elliott transformation is thus a first-order correction of the approximate equations for the effect of transverse curvature, allowing the boundary-layer thickness to be of the same order as the body radius.

2.4 TRANSFORMATION OF THE COMPRESSIBLE BOUNDARY-LAYER EQUATIONS

In order to simplify further the equations, the Stewartson transformation (ref. 4) reduces the equations to a set of equations for an incompressible flow. The following analysis is presented in terms of the Probstein-Elliott coordinates, \tilde{x} and \tilde{y} , with the understanding that in the two-dimensional case $x = \tilde{x}$ and $y = \tilde{y}$.

In the Stewartson transformation the following variables are introduced:

$$X = \int_{0}^{\widetilde{X}} \frac{p_{e}^{a}_{e}}{p_{e_{o}}^{a}e_{o}} d\widetilde{x} \qquad Y = \int_{0}^{\widetilde{Y}} \frac{\rho_{e}^{a}_{e}}{\rho_{e_{o}}^{a}e_{o}} \frac{\rho}{\rho_{e}} d\widetilde{y} \qquad (17)$$

$$u = \frac{a_{e_o}}{a_{e}} \tilde{u}$$
 (18)

$$V = \frac{p_{e_o}}{p_e} \left(\frac{a_{e_o}}{a_e}\right)^2 \tilde{u} \frac{\partial}{\partial \tilde{x}} \int_0^{\tilde{y}} \frac{\rho_e a_e}{\rho_{e_o} a_{e_o}} \frac{\rho}{\rho_e} d\tilde{y} + \frac{p_{e_o} a_{e_o}}{p_{e_o} a_{e_o}} \frac{\rho}{\rho_{e_o}} \tilde{v}$$
(19)

With these the boundary conditions become:

$$\begin{array}{lll} \widetilde{\mathbf{y}} = \mathbf{0}; & \mathbf{U} = \mathbf{V} = \mathbf{0} \\ \mathbf{v} & \mathbf{v} & \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v} \\ \mathbf{v} & \mathbf{v$$

It is assumed that S and the eddy-viscosity parameter, β , transform directly; that is,

$$S(X,Y) = S(\widetilde{x},\widetilde{y})$$
 (20)

$$\beta(X,Y) = \beta(\tilde{x},\tilde{y}) \tag{21}$$

It is easily shown, using relations (17) through (21) and the perfect gas assumption along with the relations

$$\frac{\mu}{\mu_{e_o}} = C \frac{T}{T_{e_o}}$$
 (22)

and

$$\frac{\partial \mathbf{p}}{\partial \mathbf{p}} = 0 \tag{23}$$

that the boundary-layer equations in the Stewartson plane are:

Continuity

$$\frac{\partial U}{\partial x} + \frac{\partial V}{\partial y} = 0 \tag{24}$$

Momentum

$$U \frac{\partial U}{\partial X} + V \frac{\partial U}{\partial Y} = (S+1)U_e \frac{dU_e}{dX} + CV_e \frac{\partial}{\partial Y} \left[(1+kt\tilde{y})\beta \frac{\partial U}{\partial Y} \right]$$
 (25)

Energy

$$U \frac{\partial S}{\partial X} + V \frac{\partial S}{\partial Y} = C_{V_{e_{o}}} \frac{\partial}{\partial Y} \left[(1 + kt\tilde{Y}) A \frac{\partial S}{\partial Y} \right]$$

$$+ C \frac{{}^{V_{e_{o}}}}{{}^{H_{e}}} \frac{a_{e}^{2}}{a_{e}^{2}} \frac{\partial}{\partial Y} \left[(1 + kt\tilde{Y}) BU \frac{\partial U}{\partial Y} \right]$$
(26)

The coordinate \tilde{y} is not transformed in the transverse curvature terms because integration of the equations across the boundary layer is anticipated and only corresponding values are needed in those terms. The Chapman-Rubesin parameter, C, is assumed to be at most a function of x. In the work presented herein, C is a constant evaluated at the wall temperature; that is,

$$C = \frac{\mu_{w}}{\mu_{e_{o}}} \frac{T_{e_{o}}}{T_{w}} = \left(\frac{T_{w}}{T_{e_{o}}}\right)^{1/2} \left(\frac{T_{e_{o}} + T_{s}}{T_{w} + T_{s}}\right)$$
(27)

where Sutherland's law is used to evaluate the viscosity.

$$\mu = \lambda \frac{T^{3/2}}{T + T_s} \tag{28}$$

where λ and T_s are constants.

In the remainder of this report, the solution of the energy equation (26) will be approximated by the Crocco relation

$$S = S_{\mathbf{w}} \left(1 - \frac{\mathbf{U}}{\mathbf{U}_{\mathbf{p}}} \right) \tag{29}$$

Thus, the velocity profiles found to be valid for incompressible, two-dimensional turbulent boundary layers can be used by simply transforming the input quantities to the incompressible plane, performing the calculation for an equivalent incompressible boundary layer, and then transforming the results back to the compressible plane, and for an axisymmetric flow, back to the axisymmetric coordinates.

2.5 DEVELOPMENT OF INTEGRAL BOUNDARY-LAYER METHOD

2.5.1 Integral Equations

The integral method used herein was described in detail in reference 5. Families of integral equations are derived by eliminating V between the momentum and continuity equations and then taking weighted integrals of the resulting equation across the boundary layer.

$$\int_{0}^{\delta} \left[UU_{X} - U_{Y} \int_{0}^{Y} U_{X} d\eta - (S+1)U_{e}(U_{e})_{X} - \nu(\beta U_{Y})_{Y} \right] f(Y) dY = 0$$
 (30)

In the present case, the functions

$$f = Y^n$$
; $n = 0,1$ (31)

produce the momentum and moment of momentum integral equations, respectively.

2.5.2 <u>Velocity Profiles</u>

The Y dependence of the integral equations is eliminated by substituting an appropriate parametric formulation for the velocity profiles. The function used for the present theory is a modification of Coles' family (ref. 6) with a laminar sublayer added and the wake function approximated analytically.

$$U = U_{\tau} [2.5 \ln(1 + Y^{+}) + 5.1 - (3.39Y^{+} + 5.1) \exp(-0.37Y^{+})]$$

$$+ U_{\beta} \sin^{2}(\frac{\pi}{2}) \frac{Y}{\delta_{i}}$$
(32)

The parameter U_{τ} is the friction velocity,

$$U_{\tau} = \frac{C_{f}}{|C_{f}|} U_{e} \sqrt{\frac{C_{f}}{2}}$$
 (33)

The variable Y^{+} is defined to account for the axisymmetry of the flow

$$Y^{+} = \frac{|U_{\tau}|Y}{v_{e_{\Omega}}} \left(\frac{L}{r_{w}}\right)^{k}$$
 (34)

The other parameters in equation (32) are δ_i , the boundary-layer thickness and U_{β} a wake velocity. The exponential terms and the additional unit in the logarithmic term provide a smooth transition from the turbulent flow to the wall through a laminar sublayer.

2.5.3 Eddy Viscosity

The eddy-viscosity model used in this work is an extension of the two-layer model used by Kuhn (ref. 2) including an

intermittency function for the outer layer and a modification of the outer layer for adverse pressure gradients and separated flows. In the inner layer of attached flows, the eddy-viscosity parameter, β , is represented by an exponential expression based on the law of the wall. In the outer layer Clauser's expression, modified for adverse pressure gradients, is used along with an intermittency function giving

$$\beta = [0.013 + 0.0038 \exp(-\delta_{\mathbf{k}}^{*} \mathbf{p}_{\mathbf{X}}^{15\tau_{\mathbf{w}}})] \mathbf{U}_{\mathbf{e}} \delta_{\mathbf{k}}^{*} / [1 + 5.5(\tilde{\mathbf{y}}/\delta)^{6}]$$
 (35)

For favorable pressure gradients, the exponential term in equation (35) is taken to be unity.

For separated flows, the eddy viscosity across the entire layer is represented by a relation based on the velocity profile above the U=0 line.

$$\beta = 0.013[1 + 5.5(\tilde{y}/\delta)^{6}]^{-1} \frac{U_{e}}{v} \int_{Y_{u=0}}^{\delta} \left(1 - \frac{U}{U_{e}}\right) dy$$
 (36)

2.5.4 Transitional Eddy Viscosity

Transition from laminar to turbulent flow is calculated by letting the eddy viscosity change from a laminar viscosity to a fully turbulent value over a short distance according to the relation

$$\beta_{t} = [1 - \exp(-K(x - x_{t})^{2})](\beta_{T} - 1) + 1$$
 (37)

where

 β_{+} is the transitional eddy viscosity

 $eta_{f T}$ is the turbulent eddy viscosity

 x_{+} is the location of the beginning of transition

AED C-TR-77-72

and

$$K = \frac{0.0001}{\delta_{t}^{2}}$$

where

 δ_{t} is the boundary-layer thickness at x_{t} .

2.5.5 Equations Solved

Substitution of equation (32) into the two equations produced by equations (30) and (31) produces two ordinary differential equations for the variation of the variables U_{τ} , U_{β} , δ_{i} , and U_{e} with x. A third equation produced by evaluating equation (32) at Y = δ_{i} allows the elimination of U_{β} from the equations, leaving a set of two equations

$$A_{11}(U_{\tau})_{x} + A_{12}\delta_{i_{x}} + A_{13}(U_{e})_{x} = -U_{\tau}|U_{\tau}|/U_{e}\delta_{i}$$
 (38)

$$A_{21}(U_{\tau})_{x} + A_{22}\delta_{i_{x}} + A_{23}(U_{e})_{x} = -\frac{v}{U_{e}\delta_{i}^{2}} \int_{0}^{\delta_{i}} \beta U_{Y} dY$$
 (39)

Anticipating the development of a viscous-inviscid interaction, the velocity, $U_{\rm e}$, is considered to be a dependent variable. The coefficients ${\rm A}_{ij}$ are functions of the variables ${\rm U}_{\tau}$, ${\rm A}_{i}$, and ${\rm U}_{\rm e}$. The usual procedure for solving equations (38) and (39) for attached boundary layers is to prescribe the pressure distribution or the free-stream velocity distribution, ${\rm U}_{\rm e}$. However, if separation occurs, the pressure distribution cannot be prescribed arbitrarily in the separated region. If an adverse pressure gradient is prescribed for an attached boundary layer, the value of ${\rm U}_{\tau}$ can approach zero. When ${\rm U}_{\tau}$ vanishes, the coefficients ${\rm A}_{11}$ and ${\rm A}_{22}$ in equations (38) and (39) also vanish, producing a singularity. The singularity can be removed by rearranging the equations so that ${\rm U}_{\tau}$ is not

a dependent variable. One method of accomplishing this is simply to rearrange the equations so that \mathbf{U}_{τ} can be prescribed and $\mathbf{U}_{\mathbf{e}}$ can be calculated as a dependent variable as shown in reference 7.

Another method of avoiding the singularity at $U_{\tau}=0$ is used in the method described herein. The displacement thickness, δ^* , is expressed in terms of U_{τ} , δ_i , and U_e and the result is differentiated with respect to x, producing a third equation.

$$A_{31}(U_{\tau})_{x} + A_{32}\delta_{i_{x}} + A_{33}(U_{e})_{x} + U_{e}\delta_{x}^{*} = 0$$
 (40)

where the A_{3i} are functions of U_{τ} , δ_{i} , and U_{e} and A_{31} vanishes when $U_{\tau}=0$. It can be shown that A_{11}/A_{31} and A_{21}/A_{31} are both finite when $U_{\tau}=0$. This allows the three equations, (38), (39), and (40), to be reduced to two ordinary differential equations in the four dependent variables, U_{τ} , δ^{*} , δ_{i} , and U_{e} . The resulting equations are:

$$\frac{A_{11}}{A_{31}} U_{e} \delta_{x}^{*} + \left(\frac{A_{11}}{A_{31}} A_{32} - A_{12}\right) \delta_{1x} + \left(\frac{A_{11}}{A_{31}} A_{33} - A_{13}\right) (U_{e})_{x} = \frac{U_{\tau} |U_{\tau}|}{U_{e} \delta_{1}}$$
(41)

$$\frac{{{{\bf A}_{21}}}}{{{{\bf A}_{31}}}}\; {{\bf U_e}} \delta {{\bf x}}^{*} + \left({\frac{{{{\bf A}_{21}}}}{{{{\bf A}_{31}}}}\; {{\bf A}_{32}} - {{\bf A}_{22}}} \right) \; \delta_{{\bf i_x}}$$

3.50

a band Lag

$$+\left(\frac{A_{21}}{A_{31}}A_{33}-A_{23}\right)(U_e)_{x} = \frac{v}{U_e\delta_{i}^{2}}\int_{0}^{\delta_{i}}\beta U_{y}dy \qquad (42)$$

The value of U_{τ} can be obtained directly from known values of δ^* , δ_i , and U_e by solving the nonlinear relation

$$\delta^* = f(U_T, \delta_i, U_e) \tag{43}$$

Prescribing the distribution of δ^* in equations (41) and (42) and obtaining U_{τ} from equation (43) is equivalent to prescribing U_{τ} as described previously.

2.5.6 Method of Solution of Equations

The equations (38) and (39), or (41) and (42) are integrated numerically using a fourth-order Adams-Moulton predictor-corrector integration with a fourth-order Runge-Kutta scheme used to obtain starting values. By doubling or halving the integration step size, the integration is capable of some optimization of the integration. Thus, numerical errors are kept within certain bounds by dividing the integration step by 2 whenever the error is too large and multiplying the interval by 2 whenever less accuracy is necessary than is being obtained. The step size is allowed to decrease to as small a value as 10^{-6} before the calculation is terminated.

3.0 INVISCID-FLOW MODEL

The inviscid-flow method employed herein is the finite-difference solution of the full potential equation described in references 1 and 8. The computer program used is that described in reference 1 with minor modifications to accommodate the iteration between the inviscid and boundary-layer flows. The detailed derivation of the flow equations, the calculative method, and the computer program are contained in references 1 and 8 and will not be repeated here. A general description of the program is summarized here from reference 1.

"One of the important considerations when trying to solve the full potential equation is the choice of a coordinate system. For complex three-dimensional shapes cartesian coordinates may be best; however, for simpler two-dimensional or axisymmetric shapes the use of a coordinate transformation such that the body lies along a coordinate line can greatly simplify the application of the exact boundary condition at the body surface. The program described in this paper uses a body-normal coordinate system for closed bodies. For open bodies (i.e., bodies with a sting or simulated wake) it uses a body-normal system on the forebody up to the first horizontal tangent and a sheared cylindrical coordinate system aft of that point. This coordinate system is suitable for closed bodies which are blunt on both ends and convex and smooth over the entire body or for open bodies which are blunt-nosed and convex and smooth up to the first horizontal tangent. It is possible to treat pointed bodies and bodies with slope discontinuities but the coordinate system is not well suited for them and their solution may not be as accurate as the blunt-body solutions."

"A stretching is applied to both the normal and tangential coordinates such that the infinite physical space is mapped to a finite computational space. Thus, the boundary condition at infinity can be applied directly and there is no need for an asymptotic far-field solution. Details about the stretching functions are given in [reference 1] appendix A."

"The general method of solution is to replace the governing second-order partial differential equation with a system of finite-difference equations, including Jameson's rotated difference scheme at supersonic points. The difference equations are solved by a column relaxation method."

"The boundary condition at the body surface is applied through the use of dummy points inside the body. Details of this computation are given in [reference 1] appendix B."

4.0 VISCOUS-INVISCID INTERACTION METHOD

Separation is the result of an adverse pressure gradient causing reversal of the low-energy, low-momentum fluid near the wall in the boundary layer. The adverse pressure gradient is determined by the inviscid flow field and is the net result of the body shape and the displacement effect of the boundary layer. Thus, the viscous and inviscid flow fields are interdependent. Accounting for this interdependence with an interaction model is made difficult by the fact that the boundary-layer equations are parabolic and therefore cannot respond to disturbances downstream of local stations, while for subsonic and transonic flows the inviscid flow is elliptical and therefore subject to influence by the entire flow field. In the method described herein, the boundary-layer and inviscid-flow methods are used alternately in an iterative scheme.

Before proceeding with the description of the iterative scheme developed in the work, it is worthwhile to consider two important results. The work of Presz (ref. 9) has shown that the displacement effect of the separated boundary layer on an afterbody can be represented by a conical surface placed between the separation and reattachment points. Reubush and Putnam (ref. 10) went a step further, and devised a calculative scheme in which the conical surface was treated as a solid surface and the boundary layer was calculated on the modified body. reversed flow was calculated and the separation prediction method used in that work was based only on the inviscid pressure distribution calculated for the real body alone and thus could not account for Reynolds number effects. Nevertheless, these methods reveal significant information about the nature of the boundary layer in the region of strong interaction. First, the boundary layer grows smoothly as it encounters the adverse pressure gradient, and second the displacement surface assumes

a condition such that its effect after separation can be approximated by a conical surface.

4.1 ESTIMATION OF SEPARATION POINT LOCATION

The first step in calculating the viscous-inviscid interaction is to calculate the inviscid flow over the plain body. The resulting distribution of the velocity at the boundary, u_e, is then prescribed for the boundary-layer calculation using equations (38) and (39). If strong adverse pressure gradients exist, the boundary-layer calculation may reach a point where the skin-friction coefficient approaches zero and the numerical calculation can proceed no further with u_e prescribed. This point is not necessarily the true location of separation, however, since the interaction with the inviscid flow has not yet been accounted for.

A better first approximation to the location of separation x_s can be found by computing the shape factor, H_{tr} .

$$H_{tr} = \frac{\int_{0}^{\delta_{i}} \left(1 - \frac{U}{U_{e}}\right) dY}{\int_{0}^{\delta_{i}} \frac{U}{U_{e}} \left(1 - \frac{U}{U_{e}}\right) dY}$$
(44)

For the velocity profiles given by equation (32) this parameter has a value of 4.0 when $U_{_{\rm T}}=0$. However, experimental measurements indicate that separation actually occurs when $H_{\rm tr}$ is approximately 2.0. This suggests that the present boundary-layer approximation is not accurate in the vicinity of the separation point. The major cause of the inaccuracy is believed to be the neglect of any upstream influence of the separated region inside the boundary layer. However, the effect of the separated region which is transmitted upstream in the boundary

layer is believed to be small compared to the effect transmitted through the inviscid flow. In this work, the first approximation to the value of x_s is the location at which $H_{tr} = 1.5$ for the inviscid velocity calculated for the plain body.

4.2 ESTIMATION OF BOUNDARY OF SEPARATED REGION

At the separation point, x_s , the skin friction is assumed to have become zero and the calculation is carried on into the separated flow using a prescribed distribution of δ^* with equations (41) to (43). The result of that calculation is a solution for the free-stream velocity (the "viscous velocity") which may or may not agree with the "inviscid velocity" produced by calculating the inviscid-flow theory. An iterative procedure is used to find the particular variation of δ^* downstream of x_s for which the "viscous velocity" and the "inviscid velocity" agree.

A two-parameter analytical formulation is used to represent the effective displacement surface between separation and a point downstream of reattachment. Thus, the effective body shape is given by

$$r = r_w + \delta^*$$
 for $0 < x < x_s$ and $x_p < x < \infty$ (45)

$$r = (r_w + \delta^*)_s + (x - x_s) \tan \theta_s$$
 for $x_s < x < x_p$ (46)

where x_p is the location of the peak inviscid pressure as given by the previous inviscid solution and θ_s is the angle of the extrapolated δ^* surface with the axis.

A first approximation to the angle, $\theta_{\rm S}$, is obtained from an expression presented in reference 10.

$$\theta_{s} = \tan^{-1}\left(\frac{\mathrm{dr}_{w}}{\mathrm{dx}}\right) + 14.4 - 4.89 \,\mathrm{M}_{s} \tag{47}$$

Downstream of x_p the free-stream velocity is again prescribed on the boundary layer (eqs. (38) and (39)) as an exponential fairing between the value at x_p and the inviscid velocity from the previous calculation.

4.3 ITERATION PROCEDURE

The method developed in this work consists of three iterations. One iteration is used to locate the separation point, $\mathbf{x_s}$. Another iteration is used to determine the angle, θ_s , of a conical displacement surface. The third iteration calculates the best solution for specific values of $\mathbf{x_s}$ and θ_s . The iteration procedure is described schematically in figure 2.

The iteration procedure consists of three cycles. In the inner cycle, the inviscid flow and the boundary layer are calculated alternately until the largest change in the δ^* solution between iterations becomes smaller than a specified percent. At each step of the cycle, the boundary-layer displacement thickness is used to calculate an augmented body shape by the relation

$$\mathbf{r}_{\mathbf{n}} = \mathbf{r}_{\mathbf{w}} + \alpha \delta_{\mathbf{n}}^{*} + (1 - \alpha) \delta_{\mathbf{n} - 1}^{*} \tag{48}$$

where r_n is the effective body radius at iteration n and α is a damping factor, usually equal to 0.5.

When the inner cycle has been terminated, the calculation is complete if no separation occurred. However, if separation is present, there exist two solutions for the free-stream velocity as described previously. The next step of the procedure is to calculate the squared deviation between the two solutions downstream of \mathbf{x}_s at 19 points.

$$s = \sum_{1}^{19} (u_{e_{V}} - u_{e_{I}})^{2} / u_{e_{O}}^{2}$$
 (49)

where u_{e_V} is the "viscous velocity" and u_{e_I} is the "inviscid velocity." This quantity is then compared with the value from the previous θ_s iteration and if a minimum has not been found, θ_s is adjusted in an appropriate manner, the boundary layer is recalculated using the new value of θ_s and the calculation reenters the inner cycle. This process is repeated until a minimum of the squared deviation, s, is found. The present program calculates the best fit for changes in θ_s within 0.5°.

When the $\theta_{\rm S}$ cycle is complete, for a given value of ${\rm x_S}$, the next step is to adjust ${\rm x_S}$ in an appropriate manner and reenter the $\theta_{\rm S}$ cycle. These cycles are repeated until the smallest value of s is found, establishing $\theta_{\rm S}$ within 0.50 and ${\rm x_S}$ within a distance equal to the value of δ^* at ${\rm x_S}$.

An alternate termination device is incorporated in the computer program to aid in keeping the cost of the solution at a minimum. If the squared deviation, s, is smaller than 0.0005 at any step of the iteration, the iteration procedure terminates.

5.0 COMPUTER PROGRAM ORGANIZATION

In this section, the general organization of the programs will be described. Specific information on data required for input and data developed for output will be described in sections 6, 7, and 8. Sample Job Control Card decks for a typical IBM 370 installation are presented in section 9.

The overall program consists of a mainline program (program 1) and two main subprograms each consisting of several subroutines. The first main subprogram is the inviscid-flow program (program 2). It is a modified version of the

program described in reference 1. The second main subprogram is the boundary-layer program (program 3). It is based on the integral theory described previously and retains the two-dimensional case as an option. The mainline program controls the iteration between the other two programs. Either of the two subprograms may be used separately, without iterating by appropriate choice of the input parameters.

Both the boundary-layer program and the inviscid-flow program require some punched card input and some input data from disc or tape data files. The data files must be identified by specific Logical Unit numbers. Each program in turn produces new data files and printed output. The general relationship of the programs and the various data files are shown in figure 3. The specific Logical Unit numbers required for input and output are listed in Table I. Two Logical Unit numbers are associated with each data file shown in figure 3. One unit is used for input, the other for output.

program 2 requires initially data from cards describing the free-stream conditions, the computational mesh and the body shape. Alternately, the program can accept the input body shape from data file 1. It can also accept an initial solution for the perturbation velocity potential from another data file (data file 2). Program 2 produces printed output lists of the appropriate flow field quantities, quantities describing the configurations and the computational mesh and several data files. Data file 2 is rewritten using the new solution for the potential. A third file (data file 3) is written containing the distribution of the axial velocity component for use by the boundary-layer program.

Program 3 requires initially the free-stream conditions and gas constants as well as parameters describing the shape of the surface over which the boundary layer is flowing. On the first iteration of a viscous-inviscid interaction, the surface shape

is the same as that for program 2. On subsequent iterations, the body shape for the boundary-layer program remains the same while that for the inviscid flow is modified by the addition of the boundary layer. Program 3 can also accept data from data files as optional input. The free-stream velocity distribution. ue, can be input from data file 3, produced by program 2. distribution of the body shape augmented by the displacement thickness can be input from data file 4. That file differs from data file 1 because it contains the raw data for $\delta^* + r_w$ versus x as calculated by the boundary-layer program while data file 1 contains the shape adjusted according to equation (48) and interpolated to the x stations of the original input shape. program 3 is being used separately from program 2 (i.e., without iterating), two additional options are available for card input. Either the free-stream velocity, u, can be input as mentioned previously, or the displacement thickness, δ^* , may be input. These options are described more fully in sections 6.2 and 7.1.

Program 3 produces as output lists of the boundary layer and flow quantities as they are calculated along the body. In addition, program 3 produces an updated version of data file 4 and the augmented body shape (data file 1) required by program 2. Data file 4 also contains a list of the velocity ratio u_e/u_{e_O} corresponding to the boundary layer.

Program 3 can be used in a two-dimensional mode if desired. However, calculation of a viscous-inviscid interaction can only be done for axisymmetric cases with the present inviscid program.

All card input pertaining to programs 2 and 3 is input through program 1. Program 1 also produces a file of the quantities needed to restart the calculation if the calculation should terminate before all iterations are completed. These data are stored on data file 5. Detailed instructions regarding restarting are presented in section 7.3.

6.0 INPUT TO THE PROGRAMS

The data required by the programs generally fall into three categories: (1) geometrical data; (2) flow field data; and (3) control parameters. The control parameters are indices for specifying options and iteration counters. It will be noted by comparison with reference 1 that a number of input quantities required for the inviscid-flow program have been eliminated in the present version. This has been done by incorporating the calculations required to obtain some of the quantities into the present code or by simply defining fixed values which have been found to be successful. Specifically, a value of 1.4 is used for the initial value of the subsonic relaxation factor, a value of 0.1 is used for the initial value of the supersonic relaxation factor and a value of 1.3 is used for the exponent in the normal coordinate stretching function. Also, it is assumed that the computational grid has equal step sizes in both coordinate directions at the nose of the body.

The general requirement of the input data is that the tabular lists of the various distributions required represent smooth curves. This is especially true of the list of body shape coordinates. The inviscid program uses cubic splines to fit the input coordinates, so those coordinates must accurately represent a smooth curve with continuous second derivatives.

6.1 TABULAR FORM

The input data required for calculating transonic boundary-layer, inviscid-flow interactions consist of several punched cards containing parameters describing the free-stream flow conditions, the computational mesh for the inviscid calculation, initial values for the boundary-layer calculation, and certain options that are available in the programs. A dictionary of the input data is presented in the next section. Table II shows

the input variables as they are to be punched on the data cards. More detailed explanation of the requirements for the inviscid-flow program are presented in reference 1 and are not repeated herein.

6.2 DICTIONARY OF INPUT VARIABLES

The variables required for input on punched cards are defined in this section in the order in which they are required. Additional details on the format of the punched data are given in Table II. The first three cards of any input data deck contain a description of the case being calculated. Any or all of these three cards may be blank, but all three are required. The remaining variables in Table II are as follows:

LPROG Integer indicating level of calculation.

- = -l Inviscid flow only.
- = 0 Inviscid-viscous interaction.
- = 1 Boundary layer only.

NRSTRT Integer indicating whether calculation is being restarted to continue a previous calculation. Only needed if LPROG = 0.

- = 0 Start from zero. Input all quantities on cards or data files as required.
- Restart. Input data file 5 (Logical Unit 11) containing data from previous iteration plus all other input data files.

NPRINT Integer indicating quantity of output to be printed (see section 8.1).

- = 0 Minimum output.
- = 1 All output.

NlMAX Integer convergence criterion for inner iteration cycle. The cycle is considered to be converged when the maximum change in δ^* between iterations is less than NlMAX percent. A value of 7 is good for most

NlMAX engineering purposes. More accuracy is obtained with (conc.) smaller values at increased cost. However, a maximum of ll iterations will be performed in the inner cycle in any case.

Nl Integer iteration counter for inner viscid-inviscid iteration.

N2 Integer iteration counter for θ_s iteration presently limited to a maximum of 20.

N3 Integer iteration counter for x_s iteration presently limited to a maximum of 20.

IBL Integer indicating how interaction calculations are to begin.

- = 3 Start with inviscid flow.
- = 0 Start with boundary layer.

MIT2 Integer number of iterations to be executed by the inviscid program in solving its relaxation equations for the first series of calculations in the inner iteration cycle. After the inner iteration cycle has been converged for the first time, the relaxation iteration limit is set equal to the value of MIT to be input subsequently. A typical value for MIT2 is 20 for interaction calculations. A larger value may be better for some transonic cases.

GAMMA Ratio of specific heats.

AMINF Free-stream Mach number.

IXY Integer number of values of coordinate pairs, XO,YO, to be input for inviscid body shape. If IXY = 0, the required shape must be input from data file 1 (Logical Unit 14). Maximum value is 100.

XO,YO Axial and radial coordinates of body shape for inviscidflow calculation, 2 per card.

AEDC-TR-77-72

The next series of variables, items 6 and 7 in Table II, are for the inviscid-flow program. Detailed information on how these data are to be obtained is contained in reference 1.

IMAX Number of grid lines in the tangential direction;

I = l is the forward stagnation line, I = IMAX is the rear stagnation line for closed bodies and downstream infinity for open bodies. For each grid refinement IMAX is increased such that IMAX_{NEW} = 2(IMAX_{OLD}) - 1. The present limit on IMAX is 81. Instructions for changing this limit appear as comments in the program listing (subroutine ONEO).

JMAX Number of grid lines in the normal direction; J = 1 corresponds to an infinite distance from the body and J = JMAX is on the body. The same formula and limit that apply to IMAX also apply to JMAX.

MIT Maximum number of iterations (complete relaxation cycles) allowed for the inviscid-flow program after complete inner cycle or when using the inviscid-flow program alone. A typical value for interaction calculations is same as MIT2. The values of MIT and MIT2 are combined for the final iteration of an interaction calculation so that a total of MIT+MIT2 relaxation cycles are performed.

MHALF Number of grid refinements to be done. For interaction calculations a value of zero should be used with a grid fine enough for adequate resolution.

KLOSE Body type.

- = 0 Open body (i.e., one with a sting or wake).
- = 1 Closed body.

NPLOT Plot trigger; NPLOT = 1 causes write on disc for input to plot routines and calling of plot routines. (The

plot routines are not included in the present version
so NPLOT = 0 should be put in.)

LREADP Integer indicating whether initial estimate of potential distribution is to be input from data file 2 (Logical Unit 13).

= 0 - no

= 1 - yes

DETAO Step size of the normal coordinate at the body.

Value of the computational coordinate, X, at the matching point of the two stretching functions used in the finite-difference scheme (see ref. 1), for open bodies only. Since X varies from zero to one, XIXM is the fraction of the total number of grid points which will be in the first stretching region (ahead of x_m). Usual value is about 0.85. The exact value used should be chosen so that one grid point, usually the one at x_m , corresponds to the boattail-sting junction.

XM Axial location, x_m , (in physical coordinates) of the junction (or matching point) between the two tangential stretching functions, for open bodies only, see reference 1. Must be less than XO(IXY). This parameter is used to concentrate computational mesh points in a certain region. The usual approach for interaction calculations is to let x_m be equal to the length of the body to the beginning of the sting, XBT.

XIM1 Approximate location of the last finite value of the tangential coordinate for open bodies; usually about 2 or 3 maximum diameters larger than the length of the body, XBT.

XBT Length of the body to the beginning of the sting.

The remaining input variables are related to the boundary-layer program alone or to the viscous-inviscid interaction method.

Axial location at which boundary-layer calculations will begin after four iterations have been calculated. The usual procedure is to start the boundary-layer calculations close to the nose of a long body at XZ (see item 15 in Table II) and then after four iterations move the starting point to XZNEW (XZNEW > XZ). In subsequent iterations, the boundary layer does not change for X < XZNEW. For long slender bodies with boattails, XZNEW can usually be near the beginning of the boattail.

DTHET Angular deviation of extraplated δ^* surface from the programmed value given by equation (47). Usual starting value is 0.0°.

LSEP Logical variable indicating whether the location of separation (XSEP) is known (.TRUE.) or not (FALSE).

XSEP Axial location of separation. Put in only if LSEP = TRUE.

IOPT Integer indicating the mode of the calculation.

- = 1 u_e is to be input.
- = 2 δ^* is to be input.

Put in a value of 1 for starting an interaction calculation.

K Integer indicating whether flow is axisymmetric.

- = 0 Two dimensional.
- = 1 Axisymmetric.

LVAR1 Integer indicator for method of input of ue when IOPT = 1.

- = 0 Input u_e (dimensional) on cards.
- = 1 Input u_e/u_{e_0} on cards.
- = 2 Input u_e/u_e from data file 3 on Logical Unit 12.

- LSHAPE Integer indicating option for calculating all initial conditions (I.C.) except u_e (see section 7.4).
 - = 0 Input initial values per LIC.
 - = 1 Calculate I.C. for flat plate.
 - = 2 Calculate I.C. for cylinder.
 - = 3 Calculate I.C. for cone.
- LIC Integer indicating initial condition options for IOPT = 1 and LSHAPE = 0.
 - = l Put in CFCl and DELTAl.
 - = 2 Put in CFCl and DELSTl.
- LDSTAR Integer indicating whether a file of $\delta^* + r_w$ is to be input.
 - = 0 No input.
 - = 1 File of $\delta^* + r_w$ versus x is required on Logical Unit 15 (data file 4).
- IUNIT Integer indicating which value of the gas constant, RGAS, and the constants in Sutherlands temperature-viscosity relation (eq. (28)) are to be used. The choice depends on whether air is the gas being calculated and the units of the input quantities.
 - = 1 Input units must be pounds, feet, seconds, and OR.
 - = 2 Input units must be pounds, inches, seconds, and OR.
 - = 3 Input units must be newtons, meters, seconds, and ^OK.

For another gas, or other units, put in anything for IUNIT and put in nonzero values of VISC, RGAS, and SCON.

- LSHPBL Integer indicating whether body shape is to be input for boundary-layer calculations.
 - = 0 XRL and RL are assumed to be the same as XO and YO. This is usually the case when starting an interaction calculation.
 - = 1 XRL and RL will be required.

NOTE: The next three variables, NVAR, XVAR, VAR, are only required on cards if LPROG = 1 and LVAR1 = 0 or 1.

NVAR Integer indicating the number of values to be input for the prescribed variable (u_e or δ^*). Maximum value is 100.

XVAR, Axial location and value of prescribed variable as VAR follows:

IOPT = 1 and LVAR1 = 0, $VAR = u_e$

IOPT = 1 and LVAR1 = 1, VAR = u_e/u_{e_O}

IOPT = 2, VAR = δ^*

EL Reference length. Needed if input data lengths are nondimensionalized. If lengths are dimensional, put in EL = 1.0.

PT Total pressure, p_{+} (lb/ft²), (lb/in²), or (newton/m²).

TT Total temperature, T_+ (°R) or (°K).

TWONTT Ratio of body surface temperature to total temperature, T_{ω}/T_{+} .

VISC Constant λ in Sutherlands formula for viscosity, equation (28). If one of the programmed values is acceptable, put in a value of 0.0. The value used will then be determined by the value of IUNIT on item number 11 as follows:

IUNIT	VISC
1	$2.27(10^{-8})$ lb sec/ft ² (°R) ^{1/2}
2	1.5764(10^{-10}) lb sec/in (${}^{0}R$) $^{1/2}$
3	$1.4582(10^{-6})$ Newton sec/m $({}^{\circ}\text{K})^{1/2}$

RGAS Gas constant. If one of the programmed values is acceptable, put in a value of 0.0. The value used will be determined by the value of IUNIT as follows:

RGAS	IUNI	T RGAS		
(conc.)	1	1716.0	ft ² /sec ²	°R
	2	247104	.0 in²/sec²	°R
	. 3	286.96	m²/sec²	°K

SCON Constant T_s , in Sutherlands viscosity law, equation (28). If one of the programmed values is acceptable, put in a value of 0.0. The value used will be determined by the value of IUNIT as follows:

IUNIT	SCON	
1	198.6	٥R
2	198.6	٥R
3	110.333	٥ĸ

DFACT Relaxation factor for adding δ^* to body, the factor α in equation (48). Usual value is 0.5. If a value of 0.0 is put in, a value of 0.5 will be used.

XZ Axial location of beginning of boundary-layer calculation.

RLEN Axial location of end of boundary-layer calculation.

Usually at least one maximum diameter larger than XBT.

XT Axial location of transition from laminar to turbulent boundary-layer flow.

Integration step size at the beginning of the boundary-layer calculation. The usual procedure is to use a small value for a new case until experience indicates whether a larger value would work. If too large an initial step is attempted, the first step of the integration procedure may calculate a negative value of δ_i and the calculation will terminate. A typical value would be $(10^{-4})\cdot \text{XBT}$.

DXP Axial interval at which velocity profiles are to be printed. If a value of 0.0 is put in, no profiles are

DXP printed. In any case, profiles will not be printed (conc.) more often than the output step specified by DXOUT.

DXOUT Axial interval at which output of the local values of u_T , δ , δ^* , θ , C_f , u_e/u_{e_O} , C_p , $\delta^* + r_w$, DX, and H_{tr} are to be printed. The output may be at irregular intervals since the output location is determined as the point where the local value of X first becomes greater than XOUT. The new value of XOUT is then calculated as XOUT = X + DXOUT. This value should be selected to produce less than 200 printed output steps for the entire length of the body.

HLIM Limit value of H_{tr} to indicate separation. Input of a blank or a value of 0.0 will cause a value of 1.5 to be used as discussed in section 4.1. If the interaction iteration has difficulty converging due to a very small separated region, it may be necessary to increase this value slightly in order to calculate a fully attached boundary layer. A value greater than 4.0 will allow the calculation to proceed to a singularity if one should occur. The calculation will terminate at that point.

CFC1 Value of skin-friction coefficient at initial boundary-layer station (see section 7.4).

DELTAl Value of boundary-layer thickness, δ (compressible), at initial boundary-layer station (see section 7.4).

DELST1 Value of boundary-layer displacement thickness, δ^* , at initial boundary-layer station (see section 7.4).

UEl Value of free-stream velocity at initial boundary-layer station.

DUEDX Value of free-stream velocity gradient at initial boundary-layer station.

NR Integer number of values of XRP and RL to be input for body shape. If NSHPBL = 0, this is assumed to be the same as IXY. Maximum value is 100.

XRP, RL Axial and radial coordinates of body shape for boundarylayer calculation. If LSHPBL = 0, these are assumed to be the same as XO and YO, respectively. For twodimensional configurations, these represent the x and y coordinates of a surface measured from a reference plane.

7.0 PROGRAM OPTIONS

Several optional modes of calculation are available through the input parameters. A description of the options and the corresponding values of the pertinent parameters follows.

7.1 BOUNDARY-LAYER OPTION

To use only the boundary-layer program, put in the three card description, then the first value on the fourth input data card should be:

LPROG=1 (see Table II)

The remaining variables shown on item number 2 in Table II are not required. The remaining cards would be those corresponding to item 3 and items 11 to 19 as described in Table II. With this option, the user has the choice of specifying either the free-stream velocity, \mathbf{u}_{e} , or the displacement thickness, δ^* , through the variables NVAR, XVAR, and VAR on items 12 and 13. The boundary-layer calculation can be restarted at any station by inputting the values of the variables at that station as listed in the output. The calculated list of $\delta^* + \mathbf{r}_{w}$ and $\mathbf{u}_{e}/\mathbf{u}_{e_{O}}$ will be written on Logical Unit 10 (data file 4) when the calculation terminates.

Another method is also available for calculating the boundary layer alone. The boundary-layer step of a viscid-inviscid iteration can be executed separately. The appropriate values on the fourth card would be:

LPROG= 0

NRSTRT = 0 or 1

NPRINT = 0 or 1

N1MAX = 100

N1 = 1

N2 = 21

N3 = 21

IBL = 0

MIT2 (not needed)

This option requires input of all quantities as though the iterative sequence were to be completed. With the values just described, only the boundary layer will be calculated and then the run will be terminated. If it is desired to continue the iteration, simply make NlMAX equal the desired convergence percentage, make N2 and N3 less than 21, and put in an appropriate value for MIT2. The free-stream velocity distribution must be provided on Logical Unit 12 for this case. All other optional inputs are the user's choice.

7.2 INVISCID-FLOW OPTION

To use only the inviscid-flow program, put in the three card description, then put in LPROG = -1 on the fourth card (item number 2 in Table II). Of the remaining values on that card, only NPRINT is required. The value of NPRINT is the user's choice. After the first four cards only the data for items 3 to 7 as described in Table II and section 6 are required for this option.

7.3 VISCID-INVISCID ITERATION OPTION

To use both the boundary-layer and the inviscid-flow programs iteratively, put in LPROG = 0 and all other quantities as appropriate. Such iterations can be started with only the body shape and free-stream flow quantities known and may be restarted to continue a prematurely terminated iteration. Several options are available to the user for restarting an unfinished iteration. See section 10.2 for an example of The simplest option is to put in NRSTRT = 1 restarting. the second value on the fourth input data card and to provide the required input data files on Logical Units 11, 12, 13, 14, and 15 (see fig. 3 and Table I). The required values of the remaining variables on card number 4 are printed periodically in the output. See section 8.1, step 20 of the output list. The particular set of values needed for restart is the last set printed before termination. The only other data required for restarting are the three-card description of the case. calculation then proceeds from where the previous iteration stopped. Another method of restarting would be to omit the restart file and put in NRSTRT = 0. The user can then vary any of the other input quantities, using the data files or punched cards as desired. Note that the calculation terminates when N2 or N3 reach a value of 21. The value of N1 increases continuously throughout the calculation while the value of N2 is reset to 1 each time the θ_s cycle is converged. iteration cycle has not converged when N3 reaches; the value of 21, that value must be decreased in order to continue.

7.4 BOUNDARY-LAYER INITIAL CONDITIONS

Initial values of boundary-layer quantities can be obtained in several ways. The user can obtain values of the skin-friction coefficient, C_f , and either the boundary-layer thickness, δ , or the displacement thickness, δ^* . These are shown on item 16 in Table II. The appropriate values LSHAPE = 0 and LIC = 1 or 2 are then punched on the card corresponding to item 11. For the case when no other source of this information is available, formulas have been included in the program based on the Blasius solution for laminar boundary layers and based on one-seventh power law velocity profiles for turbulent flows. These formulas are only available if u_e is being specified (IOPT = 1). The basic formulas calculate C_f and δ in the transform plane (incompressible, two-dimensional). The formulas are as follows:

Laminar Flow

$$c_{f_{i}} = \frac{0.664}{\sqrt{\frac{U_{e}}{v_{e_{o}}}}}$$
 (50)

$$\delta_{i} = \frac{5x}{\sqrt{\frac{U_{e}}{v_{e}}} x}$$
 (51)

Turbulent Flow

$$c_{f_i} = 0.0592 \left(\frac{U_e}{v_{e_o}} x\right)^{-0.2}$$
 (52)

$$\delta_{i} = 0.37 \times \left(\frac{U_{e}}{v_{e_{O}}} \times \right)^{-0.2}$$
 (53)

These formulas provide initial values for boundary layers on flat plates. They are chosen by inputting LSHAPE = 1. For other geometries, the value of the x coordinate is transformed. Thus, LSHAPE = 2 chooses the values for a circular cylinder, where

$$x = x_a \left(\frac{r_w}{L}\right)^2 \tag{54}$$

where x_a is the axial coordinate and LSHAPE = 3 chooses the values for a cone, where

$$x = \frac{1}{3} x_a \left(\frac{r_w}{L}\right)^2 \tag{55}$$

These formulas have been found to be quite adequate for calculating flows over long bodies. Small initial errors in the calculated boundary layer become negligible in a few boundary-layer thicknesses.

8.0 PROGRAM OUTPUT

8.1 STANDARD OUTPUT

Several options are available for output from the programs. The parameter NPRINT on item number 2 in Table II chooses either all the available output (NPRINT = 1) or only that essential for monitoring the progress of an iterative calculation. The parameter DXP on item 15 controls the printing of boundary-layer velocity profiles. For iterative calculations, the output from the inviscid-flow program is controlled by NPRINT only on the first iteration (Nl = 1). For subsequent iterations, only the short form output is printed as if NPRINT = 0.

The complete program output is presented in the following list. Steps 1-10 are always printed for the first iteration.

Of the remaining steps, those denoted by an asterisk (*) are those printed when NPRINT = 0.

- 1. Three-line title or description.
- 2. List of all values of integers or first data card.
- 3. List of Body Geometry input.
- 4. List of other input values for inviscid flow.
- 5. List of input values for boundary-layer calculation.
- 6. List of Body Shape data for boundary layer.
- 7. List of other boundary-layer input quantities.
- 8. List of Variables used in inviscid-flow calculation.
 This includes the body geometry and other parameters.
- 9. Computed geometric parameters in normal direction for inviscid flow.
 - J Normal grid index.
 - AN Normal coordinate.
 - G Stretching function derivative (refs.1 and 8).
 - GH Stretching function derivative at half intervals.
- 10. Computed geometric parameters in tangential direction.
 - I Tangential grid index.
 - S Arc length along reference surface
 - X Axial coordinate.
 - Y Radial coordinate.
 - THET Angle of reference coordinate surface, θ .

 For closed bodies, θ is the same as the body angle, $\theta_{\rm B}$. For open bodies, $\theta=\theta_{\rm B}$ on the forebody and $\theta=0$ on the afterbody.
 - THETB Body angle, θ_{B} .
 - AK Surface curvature on closed bodies. For open bodies AK is the surface curvature on the forebody and AK = $-(d^2r_w/dx^2)$ on the afterbody.

10. F (conc.)

- Derivative of the tangential stretch function (refs. 1 and 8).

*11. Inviscid relaxation iteration history.

IT - Iteration number.

DPMAX - Maximum ϕ correction, $\max_{ij} |\phi_{ij}^{IT} - \phi_{ij}^{IT-1}|$

ID, JD - I and J location of DPMAX.

RMAX - Maximum residual, max R ij , where R ij is the right-hand side of the difference equation.

IR, JR - I and J location of RMAX.

ISUB, ISUP - Indicates if maximum residual occurred at a subsonic or supersonic point.

RAVG - Average value of the residual.

RF1 - Relaxation factor for subsonic points.

QF3 - Relaxation factor for supersonic points.

NS - Number of supersonic points.

SEC/CY - Time for iteration cycle.

- 12. List of solution of perturbation potential.
- *13. Tabulated values of surface pressure coefficient, Cp,

 Mach number, and axial velocity on the body along with
 a rough plot of Cp along the body. This plot is
 distorted in the axial direction because it is for
 equal spacing in the computational space. The asterisks
 show the level of sonic Cp.
- *14. Drag coefficient by trapezoidal and Simpson integration of the Cp's on the real body. The displacement surface is removed for calculation of the drag.

(NOTE: If the two values differ greatly, it is probably due either to the computational mesh for the inviscid flow being too coarse or the inviscid relaxation being not sufficiently converged.)

- 15. Mach number chart of the flow field in the computational plane. Numbers printed are the Mach number multiplied by 100. The I values are from top to bottom and the J values are from left to right.
- 16. Coordinates x and y of the sonic line.
- 17. Boundary-layer reference velocity, u_{e_0} , and unit Reynolds number, R_{e_0}/L .
- *18. List of boundary-layer quantities with profiles at intervals governed by DXP.

AX - Axial distance from the nose, x.

UTAU - Friction velocity, u...

DELTA - Boundary-layer thickness, δ .

DELST - Displacement thickness, δ^* .

THETA - Momentum thickness, θ .

CF - Skin-friction coefficient, C_f.

UE/UZ - Free-stream velocity ratio, u_e/u_{e_0} .

CP - Surface pressure coefficient, Cp.

DELST+R - Augmented body radius, $\delta^* + r_w$.

DX - Integration step size.

HTR - Transformed shape factor, δ_i^*/θ_i .

*19. Quantities showing status of inner iteration.

XMAX - Location of maximum change in boundary layer δ^* from previous iteration.

DPMAX - Maximum change in δ^* .

DSMAX - Value of δ^* at XMAX.

- *20. Quantities needed for restart. These are the values required on input card number 4. Note, however, that the restart procedure requires the particular set of these values which is the last to be printed before termination if the restart file (data file 5) is to be used (see section 10.2).
 - 21. Rough plot and list of u_{e_V} and u_{e_I} . This is printed at the end of the inner iteration cycle whenever a new comparison is being made between the viscous and inviscid velocities.

8.2 SPECIAL OUTPUT MESSAGES

Several special messages are contained in the output to call attention to specific conditions that may occur. The messages are listed in this section with instructions about what to do when they are encountered.

(1) -----DIVERGENCE.RMAX EXCEEDS RCHEK.

GO DIRECTLY TO JAIL. DO NOT PASS GO.

DO NOT COLLECT \$200.----

This message is printed by the inviscid-flow program if the relaxation procedure diverges. Check all input to verify that it is correct. If no obvious errors appear, the difficulty is probably either in the choice of parameters for the computational mesh, or the smoothness of the data defining the body shape.

(2) RF1 DECREASED TO _____ BECAUSE 10-CYCLE AVG FOR RMAX INCREASED.

This message refers to the subsonic relaxation factor in the inviscid-flow program. The initial value is 1.4. The value is automatically reduced by 10 percent if: (1) the maximum residual, averaged over 10 cycles, is greater than that for the previous 10 cycles and (2) the last maximum residual occurred at a subsonic point.

(3) QF3 INCREASED TO _____ BECAUSE 10-CYCLE AVERAGE OF RMAX INCREASED.

This message refers to the supersonic damping factor in the inviscid-flow program. The initial value is 0.1. The value is automatically increased if: (1) the maximum correction, averaged over 10 cycles, is greater than that for the previous 10 cycles, and (2) the last maximum residual is at a supersonic point.

(4) INPUT FROM TAPE13 HAS INCOMPATIBLE DIMENSIONS

This message is printed if the dimensions of the ϕ_{ij} solution read from Logical Unit 13 (data file 2 in figure 3) are not the same as the values of IMAX and JMAX put on item number 6 in Table II.

(5) ****ITERATION FOR BOUNDARY LAYER/INVISCID FLOW EQUILIBRIUM CONVERGED

This message is printed whenever the maximum change in δ^{*} between iterations is less than the specified percent.

(6) METHOD FOR CALCULATING UTAU IN DERIV DOES NOT CONVERGE

This message refers to the iteration used to solve equation (43) for U_{τ} when δ^* is prescribed in the boundary-layer calculat on. The only known cause of the iteration failing to converge is an error in the input data.

(7) DELTAI HAS BECOME NEGATIVE STOP INTEGRATION, PRINT PROFILE AT PREVIOUS STEP

This message refers to the transformed boundary-layer thickness, δ_i . The error condition may occur due to the initial integration step size DXZ being too large. Another possible cause might be a too sudden change in the body shape, or in the prescribed u_e or δ^* distribution.

(8) DELTA HAS BECOME NEGATIVE STOP INTEGRATION, PRINT VALUES AT PREVIOUS STEP

This message is not expected to occur in the finished program. If it does, check the input data carefully.

(9) INTEGRATION INTERVAL HAS BECOME TOO SMALL.

This message usually occurs when the singularity at $U_{\tau} = 0$ is approached in a positive pressure gradient with u_{e} prescribed. It may also occur under certain other conditions.

(10) METHOD FOR CALCULATING INITIAL VALUE OF DELI DOES NOT CONVERGE

When initial values of C_f , δ , or δ^* are known, the calculation must solve an integral equation for the initial value of the transformed thickness, δ_i . This is done by iteration in a similar manner as for u_τ described in message (6). If the iteration does not converge, it is usually due to errors in the input quantities.

(11) INTERMEDIATE RESULTS OF THETA ITERATION

This message is printed at the end of each step of the $\theta_{\rm S}$ cycle. It is followed by the current value of the $\theta_{\rm S}$ increment, DTHET and the value of the squared deviation, DIFFS.

(12) FINAL RESULTS OF THETA ITERATION

This message is printed whenever the $\theta_{\rm S}$ cycle discussed in section 4.3 has converged. The message is followed by a list of the values of XSEP, DTHET, and the squared error for the best solution of that cycle.

(13) FINAL RESULTS OF XSEP ITERATION

This message is printed whenever the least squared error has been found for the x_s cycle discussed in section 4.3. When this condition occurs, the values of θ_s and x_s are set

to those corresponding to the best solution and the calculation reenters the inner cycle to perform a final iteration sequence. The final output of the inviscid-flow and boundary-layer solutions then correspond to the final converged solution.

This message is printed whenever the squared error is less than 0.0005 at any stage of the iteration. The inviscid and viscous solutions immediately preceding this message are then the best solutions of the calculation procedure.

(15) SKIN FRICTION HAS BECOME NEGATIVE IN AN INCORRECT MANNER. CHECK ALL INPUT CAREFULLY

This message will be printed if the skin-friction coefficient changes sign suddenly. This has been known to occur on rare occasions when the friction was approaching zero and the singularity did not cause the integration step size to decrease sufficiently to stop the calculation before a negative value of $\mathbf{C}_{\mathbf{f}}$ was calculated. In such a case the calculation may be all right. The condition has also occurred at other times when an input error caused a discontinuity in the prescribed $\mathbf{u}_{\mathbf{e}}$.

9.0 PROGRAM OPERATING PROCEDURE

In this section, the construction of card decks for operation of the computer programs is described. First, a general description of the operations required is given. Then the specific Job Control cards needed for operation on an IBM 370 computer are listed. The same card decks should be applicable at any 370 installation with minor modifications.

9.1 GENERAL JOB CONTROL SEQUENCE

The following list is the general Job Control procedure that would be required to run the programs for a complete viscid-inviscid interaction calculation. The reader is referred to figure 3 and Table I.

- 1. Create partitioned data sets for restart files (files 1-5 in figure 3).
- 2. Define units 2, 3, 8, 9, and 10. These unit numbers are needed for output.
- 3. Define units 11, 12, 13, 14, and 15 if NRSTRT = 1 in the input data. These unit numbers correspond to the input files. They contain data created in a previous run.

For starting an initial calculation, the partitioned data sets would be created in a separate operation. Then, since no data would be on file, only units 2, 3, 8, 9, and 10 need to be defined. For restarting an iterative calculation, all data files would exist, so units 11 to 15 must also be defined.

To execute the boundary-layer program alone, unit 10 must be defined in order to output the $\delta^* + r_w$ and u_e/u_{e_O} list. Unit 12 must be defined when LVAR1 = 2, and unit 15 must be defined when LDSTAR = 1.

To execute the inviscid program alone, units 2 and 8 must be defined. Unit 13 is also required when LREADP = 1, and unit 14 is required when IXY = 0.

9.2 JOB CONTROL EXAMPLES

In this section, specific examples of Job Control cards used for the operations discussed previously are presented. In the examples, the computer program is referred to as "ITER" with the source code names "SITER" and the load module or binary

version named "BITER". The account ID used in the examples is WYL.XM.KOl. Logical units 5 and 6 are the standard input/output file numbers. It is not necessary to specifically define these unit numbers in the JCL deck.

9.2.1 Creating Partitioned Data Sets

Partitioned data sets for use as input/output disk files must be created before the normal program operation can proceed. The following procedure is suggested:

Use IBM Utility Program IEFBR14.

Use default values for DCB (DSORG=PO, RECFM=VS).

On 3330 disk, use SPACE in tracks as follows (refer to figure 3 and Table I for explanation of file numbers):

```
VELBOD (File 3) SPACE = (TRK, (2,1,10))

RESTRT (File 5) SPACE = (TRK, (10,2,10))

PHI (File 2) SPACE = (TRK, (20,4,10))

XOFILE (File 1) SPACE = (TRK, (4,1,10))

DSFILE (File 4) SPACE = (TRK, (6,1,10))
```

Example of creating a partitioned data set called VELBOD:

```
//EXEC PGM=IEFBR14
//A DD DSN=WYL.XM.K01.VELBOD, VOL=volume,
// UNIT=3330, DISP=(,CATLG),
// SPACE=(TRK,(2,1,10))
```

9.2.2 Starting an Iteration Sequence

To start an iteration sequence, unit numbers 2, 3, 8, 9, and 10 must be defined. The specific sequence of cards used to perform the calculations presented in section 10.1 is as follows:

```
// EXEC FORTGO, PROG=ITER, VOL=volume
        LIB='WYL.XM.KO1.BITER'
//GO.FT02F001 DD DSN=WYL.XM.K01.VELBOD(RUN1).
//
        DISP=OLD
//GO.FT03F001 DD DSN=WYL.XM.K01.RESTRT(RUN1).
//
        DISP=OLD
//GO.FT08F001 DD DSN=WYL.XM.K01.PHI(RUN1),
//
        DISP=OLD
//GO.FT09F001 DD DSN=WYL.XM.K01.XOFILE(RUN1),
        DISP=OLD
//GO.FT10F001 DD DSN=WYL.XM.K01.DSFILE(RUN1),
        DISP=OLD
//GO.SYSIN DD *
        Input data cards
/:*
```

9.2.3 Restarting an Iteration Sequence

The specific cards used to perform a restart of the calculation started in the previous section are:

```
// EXEC FORTGO, PROG=ITER, VOL=volume,
// LIB='WYL.XM.KOl.BITER'
//GO.FT02F001 DD DSN=WYL.XM.KOl.VELBOD(RUN2),
// DISP=OLD
//GO.FT03F001 DD DSN=WYL.XM.KOl.RESTRT(RUN2),
// DISP=OLD
//GO.FT08F001 DD DSN=WYL.XM.KOl.PHI(RUN2),
// DISP=OLD
//GO.FT09F001 DD DSN=WYL.XM.KOl.XOFILE(RUN2),
// DISP=OLD
//GO.FT10F001 DD DSN=WYL.XM.KOl.DSFILE(RUN2),
// DISP=OLD
```

```
//GO.FT11F001 DD DSN=WYL.XM.K01.RESTRT(RUN1),
// DISP=OLD, LABEL=(,,,IN)
//GO.FT12F001 DD DSN=WYL.XM.K01.VELBOD(RUN1),
// DISP=OLD, LABEL=(,,,IN)
//GO.FT13F001 DD DSN=WYL.XM.K01.PHI(RUN1),
// DISP=OLD, LABEL=(,,,IN)
//GO.FT14F001 DD DSN=WYL.XM.K01.XOFILE(RUN1),
// DISP=OLD, LABEL=(,,,IN)
//GO.FT15F001 DD DSN=WYL.XM.K01.DSFILE(RUN1),
// DISP=OLD, LABEL=(,,,IN)
//GO.SYSIN DD *
Input data cards
/*
```

These cards were used with the example discussed in section 10.2.

9.2.4 Executing the Boundary-Layer Program Alone

The specific cards used to perform the calculations discussed in section 10.3 are listed in this section. In the example shown here, all input is assumed to be from cards, but the output list of $\delta^* + r_w$ and u_e/u_{e_0} is to be saved on unit 10. Unit 12 would be required for input if LVAR1 = 2, and unit 15 would be required if LDSTAR = 1. The cards used in the example in section 10.3 are:

```
// EXEC FORTGO, PROG=ITER, VOL=volume
// LIB='WYL.XM.K01.BITER'
//GO.FT10F001 DD DSN=WYL.XM.K01.DSFILE(RUN1),
// DISP=OLD
//GO.SYSIN DD *

Input data cards
```

9.2.5 Executing the Inviscid Program Alone

The cards used to perform the calculations discussed in section 10.4 are listed in this section. In this example, the velocity potential, ϕ , is input from unit 13, and the new solution for ϕ is output on unit 8. The calculated velocity on the body is output on unit 2. Input from unit 13 corresponds to LREADP = 1 in the card input data. In addition, unit 14 would be required for input of the body shape if IXY = 0 in the card input data. The specific cards used in the example are:

```
// EXEC FORTGO, PROG=ITER, VOL=volume,
// LIB='WYL.XM.K01.BITER'

//GO.FT02F001 DD DSN=WYL.XM.K01.VELBOD(RUN2),
// DISP=OLD

//GO.FT08F001 DD DSN=WYL.XM.K01.PHI(RUN2),
// DISP=OLD

//GO.FT13F001 DD DSN=WYL.XM.K01.PHI(RUN1),
// DISP=OLD, LABEL=(,,,IN)

//GO.SYSIN DD *

Input data cards
/*
```

10.0 NUMERICAL EXAMPLES

In this section, several example calculations are presented to aid in program checkout. An example is presented of a complete viscid-inviscid interaction, starting from the initial input and restarting after premature termination. An example is also presented of the use of the boundary-layer program alone for a two-dimensional geometry. That example also demonstrates the two options for boundary conditions, having $u_{\rm e}$ specified in the

beginning of the calculation, and δ^* specified in the second part. Input data for another sample case are also presented to demonstrate the use of the program to calculate the inviscid flow alone.

10.1 AXISYMMETRIC INTERACTION

A list of the punched card input data for a sample calculation on the boattailed body shown in figure 4 is presented in figure 5. The case being calculated is for a free-stream Mach number of 0.9. The body corresponds to the ogive-cylinder body with a circular-arc-conic boattail described in reference 11. The JCL card deck for this case has been presented in section 9.2.2. The running time for the complete calculation is about 10 minutes on the IBM 370/165.

Selected output for the sample case is shown in figure 6. A total of 27 iterations were calculated. The best solution was determined to be that corresponding to the values of $\mathbf{x}_{\mathbf{S}}$ and $\theta_{\mathbf{S}}$ used for iteration 20. Those values are used in iteration 27 to produce a final list of the solution so that it is not necessary to search through the output for the best solution. However, some caution is required in interpreting the final output. The agreement between the $\mathbf{u}_{\mathbf{e}_{\mathbf{V}}}$ and the $\mathbf{u}_{\mathbf{e}_{\mathbf{I}}}$ for the final inviscid and viscous solutions is somewhat dependent upon the accuracy of the previous calculations as determined by the input quantities NIMAX and DFACT. For the calculations shown in figure 6, NIMAX had a value of 7 and DFACT had a value of 0.5. A smaller value of NIMAX and a larger value of DFACT should improve the final agreement.

The complete list of output for this case, with NPRINT = 0, consisted of a total of 6661 lines. Output steps 1-7 as listed in section 8.1 have been omitted from this presentation since they simply verify the input data. The output pages shown are those corresponding to steps 8-21 of the set described in

section 8.1 for NPRINT = 0 on the first iteration and then a few samples of the rough plots of u_{eV} and u_{eI} at intermediate steps, including that at iteration 20 (fig. 6(j)). Finally, figure 6 concludes with the inviscid solution and boundary-layer solution corresponding to the final result.

10.2 EXAMPLE OF RESTARTING AN INTERACTION CALCULATION

The punched card input data for restarting the interaction calculation of section 10.1 after premature termination at the twelfth iteration (eleven complete iterations) is presented in figure 7. See figure 6(i) for the printed output of these quantities. The JCL card deck for this calculation was presented in section 9.2.3. Note that the iterative calculations cannot be restarted at any arbitrary iteration using the restart file, unit 11. That file and the other output files contain only the data that were output just prior to the termination.

10.3 TWO-DIMENSIONAL BOUNDARY LAYER

A list of the punched card input data for a sample calculation on the two-dimensional configuration shown in figure 8 is presented in figure 9. Note that two sets of input are presented for this case, giving an example of the options of prescribed u_e and prescribed δ^* . The data for u_e and δ^* were obtained from the experimental results of reference 12 which indicate separation occurring in an adverse pressure gradient region downstream of a shock wave. The output for the complete boundary-layer calculation are presented in figure 10. No external data files were used for input for this case. The JCL card deck for this case was presented in section 9.2.4.

10.4 AXISYMMETRIC INVISCID FLOW

The punched card input data for a sample calculation of the inviscid flow alone are presented in figure 11. These data correspond to the first inviscid-flow step of the iteration calculation described in section 10.1. The output for this case is the same as that shown in figure 6(a) through (e).

(b) Remaining 18 cards.

Figure 11. Concluded

NOMENCLATURE

- A factor defined by equation (13)
- A_{ii} coefficients in equations (38), (39) and (40) to (42)
- a speed of sound
- B factor defined by equation (14)
- C Chapman-Rubesin parameter, equations (22) and (27)
- C_f skin-friction coefficient
- Cp surface pressure coefficient
- H total enthalpy
- H_{tr} transformed boundary-layer shape factor, equation (44)
- k factor denoting two-dimensional (k = 0) or axisymmetric (k = 1) flow
- L reference length
- M Mach number
- P Prandtl number
- p pressure
- r radius
- S total enthalpy parameter, equation (4)
- s squared error factor, equation (49)
- T temperature
- T_s factor in Sutherlands viscosity relation, equation (28)
- t axisymmetric transformation factor, equation (15)
- U,V transformed velocity components, equations (18) and (19)
- U_B wake velocity factor, equation (32)

NOMENCLATURE (CONTINUED)

- friction velocity, equation (33) บ
- velocity components of physical flow field, figure 1 u, v
- transformed velocity components, equations (9) and (10) ũ, ỹ
- transformed coordinates, equation (17) X,Y
- coordinates of physical flow field, figure 1 x,y
- axial location of peak pressure downstream of boattail $q^{\mathbf{X}}$
- axial location of separation point x_s
- transformed coordinates, equations (5) and (6) \tilde{x}, \tilde{y}
- \mathbf{y}^{+} coordinate of logarithmic part of boundary layer, equation (34)
- damping factor for viscid-inviscid iterations, equation (48) α
- eddy-viscosity factor, equations (35) to (37) β
- ratio of specific heats Ύ
- boundary-layer thickness δ
- boundary-layer displacement thickness, $\int_{0}^{\infty} \left(1 \frac{\rho u}{\rho_{e} u_{e}}\right) \frac{r}{r_{w}} dy$ გ*
- boundary-layer displacement thickness, $\int_{-\infty}^{0} \left(1 \frac{u}{u_e}\right) dy$ δ*
- angle of body surface with the axis; also boundary-layer θ momentum thickness
- constant in Sutherlands viscosity law, equation (28) λ
- molecular viscosity μ
- `μ/ዮ
- density ρ

NOMENCLATURE (CONCLUDED)

- τ shear stress
- ψ stream function

SUBSCRIPTS

- e refers to boundary-layer edge
- I refers to inviscid flow
- i refers to incompressible flow
- o refers to reference conditions
- T refers to turbulent boundary layer
- t refers to transitional boundary layer; also refers to stagnation conditions
- V refers to viscous flow
- w refers to the wall or solid boundary
- x,y denotes differention with respect to x or y
